AGDEX 524

Ohio Soils with Yield Data and Productivity Index

Cooperative Extension Service
The Ohio State University

This publication has been prepared through the efforts
of agencies cooperating in the Ohio Soil Survey Program

Cooperative Extension Service
The Ohio State University

Ohio Agricultural Research and Development Center
The Ohio State University

Division of Soil and Water Conservation
Ohio Department of Natural Resources

Soil Conservation Service
United States Department of Agriculture

Material for the original publication was prepared by Samuel W. Bone, Extension Agronomist, retired, Ohio State University and L. Darrell Norton, former Technical Assistant, Ohio State University, currently Soil Scientist, USDA National Soil Erosion Laboratory, Purdue Univ., West Lafayette, Indiana.

This revision has been prepared by a committee composed of:

Ted M. Zobbeck
Extension Agronomist
Department of Agronomy
The Ohio State University

Jonathan C. Gerken
Soil Specialist
Soil Conservation Service
United States Department of Agriculture

Kenneth L. Powell
Soil Survey Publications Coordinator
Division of Soil and Water Conservation
Ohio Department of Natural Resources

Valuable comments and suggestions for improvement of the publication were also received from many agricultural specialists from throughout the state. We are especially grateful to Donald J. Eckert for his contributions in the section on the "Effects of Tillage."

Ohio Soils with Yield Data and Productivity Index

Crop yields are not a static value but change with time. These changes are influenced by technology developed through research applied by farmers. Soil properties and soil management are two important factors influencing crop yields. Technology resulting from research in crop production and soil management has resulted in yield increases for corn of about 1 bu/ac/yr during the 1940s. Through the 1950s and 1960s, this increased to 1.5 bu/ac/yr. Increases in the 1970s were 3 bu/ac/yr. Further increases can be expected in the 1980s as new production technology is developed. The yield changes of crops other than corn seem to be at a slower rate, but this may change in the future as emphasis of research is placed on soybean, small grain and forage crop production.

Ohio soils vary widely in their potential to produce crops. For example, most of the nearly level, dark soils in the western and northwestern parts of the state have an inherently high crop yield potential. Conversely, the less naturally fertile, lighter soils in eastern and southeastern Ohio have a lower potential for crop production.

It is often necessary to compare one soil to another and crop yields are frequently used. Because yields change from time to time, a relative index based on yields has been developed. The Productivity Index (PI) compares the productivity of one soil to another. In this bulletin we have used a summation of the production of five crops — corn, soybeans, wheat, oats and hay — to obtain this index. Remember that the PI or yields listed in this publication are for a particular soil after the indicated basic level of management has been applied. The PI or yields will be less where the basic level of management has not been met. In preparing this information the assumption has been made that crop yield increases will be reflected uniformly.

Soil scientists of the Division of Soil and Water Conservation, Ohio Department of Natural Resources; and the Soil Conservation Service, United States Department of Agriculture; can be helpful in interpreting and using the information contained in this publication.

BASIC ASSUMPTIONS

In developing this guide, it was necessary to identify certain conditions under which the yield levels could be achieved. We assumed that the following basic soil management practices applied to all soils:

1. The land is adapted or adaptable to the crop being grown.

2. Water relations within the soil are optimum for crop growth.
3. Fertility level and the pH of the soil are optimum for the crops being grown.
4. Appropriate tillage practices, date of planting and weed control are adapted to soil conditions and the crop grown.
5. Erosion control practices are used to decrease erosion and increase available water for the crop.

If your soils do not meet their potential, the need for soil management practices should be evaluated to determine the problem, or problems, that may be limiting the production of a particular crop. Measures should be taken to ensure that all of the basic assumptions are met. Optimal water relations include measures to ensure that adequate water is available to the crop during the growing season as well as that excess water is drained from the root zone. Timeliness of all operations influencing crop production cannot be over-emphasized. Practices must be timed so they make the greatest contribution towards higher yields and efficient production.

METHODS

This section includes some terms that may be unfamiliar to the reader. For a definition and explanation, refer to the section "Definitions" that follows this section.

The first task in developing crop yields and productivity indexes was to collect yield information from soils throughout the state. The soil names were found in county soil survey reports published since 1955. Crop yields were also collected for soils listed in unpublished soil survey reports and on soil identification legends for counties where soil surveys are currently being conducted. Yields were determined for corn, soybeans, wheat, oats and hay.

The crop yield information was collected from research conducted in recent years and modified by input from agricultural specialists throughout the state. These yields represent levels that have been achieved by 50 percent of the producers. Additional sources of crop yield information included the soil interpretations record (SCS Form No. 5) of the USDA Soil Conservation Service,

county soil survey reports, and results of field tests conducted by district conservationists and county agricultural Extension agents.

In compiling the crop yield information, we prepared guidelines to reflect yield changes in response to differences in soil texture, slope and erosion. These guidelines specify an average change that may take place. In specific situations, however, the percent change may be more or less than that listed here.

Texture

The following guidelines reflect the average percent crop yield reduction for all crops and soils listed in the table when considering soil texture alone.

| Texture* | Yield Reduction (%) |
|---|---------------------|
| SIL, L, VFSL, MU-SIL, MUCK, PEAT | 0 |
| FSL, SL, SICL, CL | 3 |
| CN-L, CN-SIL, CN-SICL, CN-CL CN-SL, CN-FSL, GR-L, GR-SL, SH-L, SH-SIL, SH-SICL, ST-L, ST-SIL | 3 |
| FS, LFS, S, LS, SIC, C | 6 |
| STV-L, STV-FSL | 9 |

* Abbreviations are defined in the "Definitions" section.

Slope

The following guidelines reflect average percent crop yield reduction as affected by differences in soil map unit slope class.

| Slope | Yield Reduction | Slope | Yield Reduction |
|-------|-----------------|-------|-----------------|
| % | % | % | % |
| 0-1 | 0 | 3-12 | 8 |
| 0-2 | 0 | 3-15 | 8 |
| 0-3 | 0 | | |
| 0-4 | 2 | 4-10 | 8 |
| 0-5 | 2 | 4-12 | 8 |
| 0-6 | 3 | | |
| 0-8 | 4 | 5-10 | 8 |
| 0-10 | 5 | | |
| 0-15 | 8 | 6-12 | 8 |
| | | 6-15 | 10 |
| 1-3 | 2 | 6-18 | 12 |
| 1-4 | 2 | | |
| 1-5 | 2 | 7-12 | 8 |
| 1-6 | 3 | | |
| 1-8 | 5 | 8-15 | 12 |
| | | 8-18 | 14 |
| 2-5 | 4 | 8-20 | 14 |
| 2-6 | 4 | | |
| 2-8 | 6 | 10-15 | 12 |
| 2-12 | 8 | 10-20 | 14 |
| | | 12-18 | 16 |
| 3-8 | 6 | | |
| 3-10 | 7 | | |

Map units greater than 18 percent slope are not recommended for crop production and were not evaluated in this guide.

Erosion

Crop yield reductions were also attributed to moderately and severely eroded slopes as defined below.

| Erosion | Yield Reduction (%) |
|--------------|---------------------|
| Slight (S) | 0 |
| Moderate (M) | 4 |
| Severe (SE) | 12 |

Calculating Soil Productivity Indexes

Soil Productivity Indexes (PI) were calculated to aid in evaluating the productivity rating of a particular soil in relation to other soils that occur in the state. The PI is a value based on the yields of the five or fewer crops listed in the table. Consequently, it reflects the relative value of those crops and is not a corn, soybean or hay index unless no other crops are specified. All crops listed can be compared by using the PI or by comparing yields of specific crops.

The PI was developed by first summing the weight per acre of crops produced for the five crops listed. If fewer than five were listed, only these crops were used to compute the PI. A factor, corresponding to our most productive soil (30,000 lb/A when five crops were considered), was then divided into this weight to arrive at a PI for that soil map unit.

Yield data are not now available for all map units recognized in Ohio. In these cases, yields were estimated by applying the appropriate yield reduction factors to closely similar soils. The following example shows how to compute the PI for Miamian silt loam, 0-2% slopes, as listed in the table. Map units with different slope or erosion were assigned yield reductions as listed in previous tables.

| Crop | Yield | Crop | Yield | Total Weight |
|----------|----------|------|------------|----------------------|
| Corn | 112 bu/A | X | 56 lb/bu. | = 6,272 |
| Soybeans | 40 bu/A | X | 60 lb/bu. | = 2,400 |
| Wheat | 52 bu/A | X | 60 lb/bu. | = 3,120 |
| Oats | 78 bu/A | X | 32 lb/bu. | = 2,496 |
| Hay | 4.8 t/A | X | 2,000 lb/t | = 9,600 |
| | | | | 23,888 lb/A |
| | | | | 23,888/30,000 = 0.80 |
| | | | | PI = 80 |

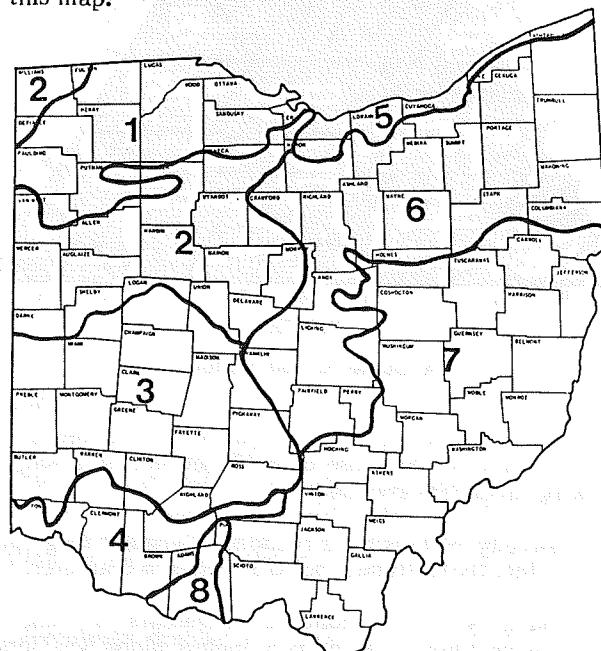

The productivity index considers soil texture, slope, erosion and natural drainage class. Variations in artificial drainage, tillage and management practices not consistent with the basic level of management specified in the "Basic Assumptions" section may change the PI.

USE OF THE YIELD AND PRODUCTIVITY INDEX TABLE

A table listing the expected yields for corn, soybeans, wheat, oats, and hay crops, and the productivity index for each map unit identified in Ohio, appears at the end of this report.

In Column 1, the soils are recorded alphabetically by series. The surface texture is listed in Column 2 (see "Definitions" section for details). Within soils of the same series, surface textures are listed from coarser to finer textures. The slope of the map unit is listed in Column 3. Within soils of the same series and surface texture, soils are listed from lower slopes to higher slopes. Column 4 records the degree of erosion that has occurred. Soils are listed from lesser erosion to greater erosion within units of the same series, surface texture, and slope.

Column 5 lists the natural drainage class of each of the soil series. The soil region or regions in which the soil occurs is listed in Column 6. The map below shows the location of soil regions in Ohio. Areas in soil regions 0, 9 and 10 are so small they could not be shown at the scale of this map.

Soil Regions and Locations

- 0 - Alluvial and Terrace soils - Western Ohio
- 1 - Soils in High Lime Glacial Lake Sediments
- 2 - Soils in Fine-Textured High Lime Glacial Drift
- 3 - Soils in Medium-Textured High Lime Glacial Drift
- 4 - Soils in Illinoian Glacial Drift
- 5 - Soils in Low Lime Glacial Lake Sediments
- 6 - Soils in Low Lime Glacial Drift
- 7 - Soils in Sandstone and Shale
- 8 - Soils in Limestone and Shale
- 9 - Alluvial and Terrace Soils - Eastern Ohio
- 10 - Organic Soils

Columns 7 through 11 list yields for common crops grown in Ohio. Development of these yields is discussed in the "Methods" section of this guide. Crop yields listed as '0' indicate the crop is not normally grown on that particular soil. Column 12 lists the productivity index for each map unit listed. Calculation of these values is also discussed in the "Methods" section.

The Yield and Productivity Index Table lists data for soil map units that are primarily composed of the soil series listed in Column 1. In some areas, soil map units are composed of two or more kinds of soil in such an intricate pattern or so small an area that it is not practical to map them separately at the selected scale of mapping. These areas are called soil complexes.

The percentage of each kind of soil in a soil complex is listed in the county soil survey report. Calculation of a weighted average PI, based on the composition of each soil in the map unit, is suggested in areas where soil complexes have been identified.

The Yield and Productivity Index Table lists soil map units based on differences in surface texture, slope and erosion class within a given soil series. In some areas, other soil differences or phases that may affect productivity have also been identified. If this occurs, the soil characteristic causing the difference is indicated in the map unit name (i.e. Westland silty clay loam, silty substratum). An evaluation of the significance of each phase can be made by your local Soil Conservation District or Cooperative Extension Service Office.

Effects of Tillage on Soil Productivity

Soil moisture is an extremely important factor in determining soil productivity, and farmers have many options available for controlling it. Most past emphasis has focused on the use of improved drainage as a means of removing excess water. On some soils, however, moisture deficits, rather than excesses, are important in limiting yield. On such soils, reduced tillage systems can increase yields and productivity.

Reduced tillage systems normally leave crop residues on the soil surface. These residues enhance infiltration, reduce evaporation from the soil surface and inhibit formation of soil crusts. All lead to an increase in soil moisture. This change in soil moisture affects the productivity of soils under different tillage systems.

In general, reduced tillage systems that leave residue on the soil surface will produce higher yields than moldboard plowing on soils classified as "well" or "moderately well" drained. Midseason moisture stress is a significant problem on these soils and reduced tillage systems generally provide some additional soil moisture for the crop. Under good management, yield increases of 10 to 15 percent are not unusual.

When adequate drainage improvements are provided, soils classified as "somewhat poorly" drained are relatively insensitive to tillage. Yields are similar, regardless of tillage system. If adequate drainage improvements are not made, however, application of some reduced tillage systems, particularly, no-till may reduce yields.

When adequate surface and subsurface drainage is provided, "poorly" and "very poorly" drained soils can produce competitive yields under reduced tillage if crops are grown following a low residue crop (soybeans, sugar beets, etc.) or a living cover, which will remove excess water. Failure to remove excess water can result in yield

reductions of up to 20 percent under reduced tillage on these soils.

Soils that do not respond to subsurface drainage are generally too wet for reduced tillage, and yields are most often reduced when such practices are applied. However, the effectiveness of subsurface drainage will be improved by good surface drainage and good soil tilth.

Effects of Artificial Drainage on Soil Productivity

One of the basic assumptions considered in this guide was that water relations were optimum for plant growth. In naturally "wet soils," this is achieved through a combination of surface and subsurface drainage. It has been estimated that excess water is a problem on nearly 60 percent of Ohio soils.

Significant reductions in yield can be expected when wet soils are not artificially drained. The exact amount of yield reduction caused by poor drainage depends on many factors. The following table lists estimated average yield reductions by drainage class and crop if drainage improvements are not met. Actual yield reductions may vary.

| Drainage | Crop | | | | |
|-------------------------------|------|----------|-------|------|-----|
| | Corn | Soybeans | Wheat | Oats | Hay |
| Reduction in Yield (%) | | | | | |
| SWP | 30 | 25 | 30 | 30 | 40 |
| P | 45 | 30 | 40 | 40 | 50 |
| VP | 30 | 25 | 30 | 30 | 40 |

Although poorly drained soils are not saturated as long as very poorly drained soils when undrained, slightly higher yields have been found on very poorly drained soils when adequate drainage has been provided. The higher yields are the result of a generally higher level of natural fertility and good soil tilth found in very poorly drained soils.

Erosion

The degree of erosion is determined by estimating how much of the original soil surface has been removed. The following categories are used in Column 4 of the yield table.

Slight -- Less than 25 percent of the original surface soil has been eroded.

Moderate -- Between 25 and 75 percent of the original surface soil has been eroded. If plowed, the plow layer is a mixture of surface soil and subsoil.

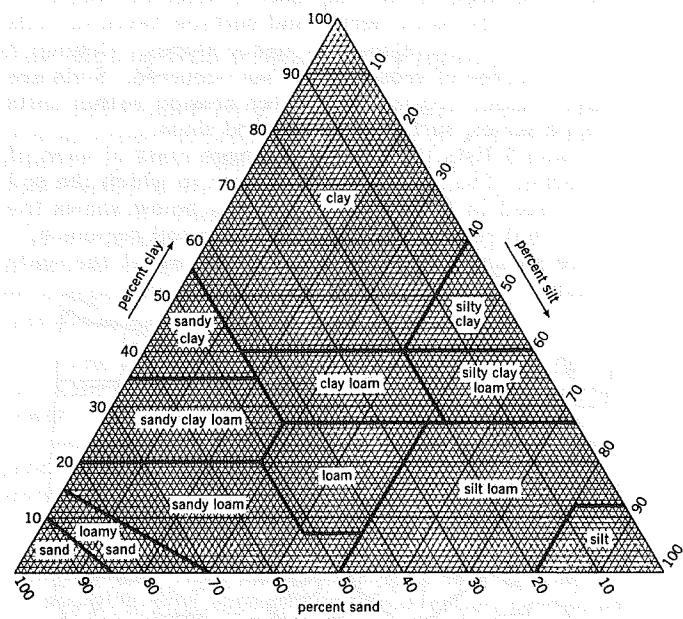

Severe -- Over 75 percent of the original surface soil has been eroded. If plowed, the plow layer is made up of mostly subsoil material.

Erosion Class Abbreviation

| Erosion Class | Abbreviation |
|---------------|--------------|
| Slight | S |
| Moderate | M |
| Severe | SE |

Texture

Soil texture is determined by the relative amounts of sand-, silt- and clay-sized particles in the soil as illustrated in the textural triangle below. Sand-sized particles range from 2 to 0.05 mm in diameter, silt particles range from 0.05 to 0.002 mm and clay particles are smaller than 0.002 mm.

A Guide to Soil Texture

If significant organic material or if particles of over 2 mm in diameter compose over 15 percent of a soil, the following modifiers are used:

Gravelly -- Soils have rounded or angular fragments, not prominently flattened, up to 3 inches in diameter.

Channery -- Soil contains fragments of thin, flat sandstone or limestone up to 6 inches along the longer axis.

Shaly -- Soils have flattened fragments of shale less than 6 inches along the longer axis.

Stony -- Soils contain rock fragments larger than 10 inches in diameter if rounded and longer than 15 inches along the longer axis if flat.

Very Stony -- Soils contain over 35 percent stones as defined above.

Mucky -- Soil contains between 10 and 20 percent organic matter.

The following table lists the texture abbreviations and modifiers used to describe soil surface texture in Column 2 of the yield table.

| Surface Textures | Abbrev. | Surface Textures | Abbrev. |
|----------------------------------|---------|---------------------|---------|
| Sand | S | Silt loam | SIL |
| Fine sand | FS | Silt | SI |
| Loamy sand | LS | Sandy clay loam | SCL |
| Loamy fine sand | LFS | Clay loam | CL |
| Sandy loam | SL | Silty clay loam | SICL |
| Fine sandy loam | FSL | Sandy clay | SC |
| Very fine sandy loam | VFSL | Silty clay | SIC |
| Loam | L | Clay | C |
| Coarse fragment modifiers | | Abbreviation | |
| Gravelly | GR - | | |
| Channery | CN - | | |
| Shaly | SH - | | |
| Stony | ST - | | |
| Very Stony | STV - | | |
| Other modifiers | | Abbreviation | |
| Mucky | MK - | | |

Example: SH-SICL Shaly silty clay loam

Drainage Class

Soil drainage class refers to the rate and duration of water movement in soils. Soils are classified into natural drainage classes based on specific ranges in duration of soil wetness and rate of water movement through the soil. The following classes are listed in Column 5 of the yield tables.

Excessively drained -- Water is removed from the soil rapidly. Enough precipitation is commonly lost from these soils to make them poorly suited for crop production

unless irrigated. Excessively drained soils are often sandy textured.

Well drained -- Water is removed from the soil readily but not rapidly. It is available to plants throughout most of the growing season, and wetness does not inhibit growth of roots for significant periods during most growing seasons. Well-drained soils are commonly medium textured.

Moderately well drained -- Water is removed from the soil somewhat slowly during some periods. Moderately well-drained soils are wet for only a short time during the growing season. They commonly have a slowly pervious layer within or directly below the subsoil.

Somewhat poorly drained -- Water is removed slowly enough that the soil is wet for significant periods during the growing season. Wetness markedly restricts the growth of crops unless artificial drainage is provided. Somewhat poorly drained soils commonly have a slowly pervious layer, a high water table, additional water from seepage or a combination of these.

Poorly drained -- Water is removed so slowly that the soil is saturated periodically during the growing season or remains wet for long periods. Free water is commonly at or near the surface for long enough during the growing season that most crops cannot be grown unless the soil is artificially drained. Poor drainage results from a high water table, a slowly pervious layer within the profile, seepage or a combination of these.

Very poorly drained -- Water is removed from the soil so slowly that free water remains at or on the surface during most of the growing season. Unless the soil is artificially drained, most crops cannot be grown. Very poorly drained soils are commonly level or depressed and are frequently ponded.

| Drainage Class | Abbreviation |
|-------------------------|--------------|
| Excessively drained | E |
| Well drained | W |
| Moderately well drained | MW |
| Somewhat poorly drained | SWP |
| Poorly drained | P |
| Very poorly drained | VP |

MAP UNIT DATA AND PRODUCTIVITY INDEX

UNDERSTANDING YOUR SOIL RESOURCES

Additional data on soils can be obtained from progress reports published by the Division of Soil and Water Conservation, Ohio Department of Natural Resources; or USDA soil survey reports published by the Soil Conservation Service. These reports are available at county Cooperative Extension Service and Soil and Water Conservation District offices. The Progress Reports and USDA Reports that follow are now available or will be available soon.
